

Section 3 | Design Vision & Concept Development

This section introduces the design vision and the final master plan, then traces how the proposal developed from broad relational ideas into a clear spatial framework. It moves from the overall vision to the concept sequence that produced the final plan.

Design Vision

Proctor Landing Park is envisioned as a flood-adaptive public landscape that links ecological performance, everyday recreation, and community life through one coordinated system. Rather than treating water, circulation, and social space as separate layers, the master plan organizes them together so the park can function as both infrastructure and experience.

The design is structured around three linked drivers. Water supports ecological function through wetlands, riparian restoration, and visible flood-compatible systems. Movement supports public health through connected paths, loops, and low-barrier access to daily activity. Draw supports social life through destinations, gathering spaces, and flexible areas that invite repeated use. Together, these systems shape a park that is resilient, legible, and built for long-term public value.

Concept Development

The final plan developed through three linked moves: a bridge concept that framed public health as the primary infrastructure, an ecological core organized around Paddy Creek, and an engaged circulation loop that translated the idea into a legible park structure with nodes of draw around the site. Together, these moves transformed the site from a disconnected open field into a coordinated system of water, movement, and draw towards a centralized scheme.

Engagement

The bridge established the project's core relationship between social and ecological infrastructure. Paddy Creek then shifted from a site constraint to the park's central organizer, creating a clearer balance between active and restorative space. Finally, the primary loop and distributed anchors turned the concept into a spatial framework that supports repeated movement, visible social life, and flood-adaptive use. The gravity of the ecological space would bring people in and as you travel away from the calm, engagement, both social and physical should increase.
